Under two different scenarios for the light scalar mesons, we investigate the transition form factors of $B(B_s)$ mesons decay into a scalar meson in the perturbative QCD approach. In the large recoiling region, the form factors are dominated by the short-distance dynamics and can be calculated using perturbation theory. We adopt the dipole parametrization to recast the q^2 dependence of the form factors. Since the decay constants defined by the scalar current are large, our predictions on the $B \rightarrow S$ form factors are much larger than the $B \rightarrow P$ transitions, especially in the second scenario. Contributions from various light-cone distribution amplitudes (LCDAs) are elaborated and we find that the twist-3 LCDAs provide more than a half contributions to the form factors. The two terms of the twist-2 LCDAs give destructive contributions in the first scenario while they give constructive contributions in the second scenario. With the form factors, we also predict the decay width and branching ratios of the semileptonic $B \rightarrow Sl\bar{\nu}$ and $B \rightarrow Sl^+l^-$ decays. The branching ratios of $B \rightarrow Sl\bar{\nu}$ channels are found to have the order of 10^{-4} while those of $B \rightarrow Sl^+l^-$ have the order of 10^{-7} . These predictions can be tested by the future experiments.

I. INTRODUCTION

Although a number of scalar states have been discovered since long time ago, the underlying structure of scalar mesons has not been well established(for a review, see [1]-[3]). In order to uncover the inner structures, many different descriptions have been proposed such as $\bar{q}q$, $\bar{q}\bar{q}qq$, meson-meson bound states or even supplemented with a scalar glueball. It is very likely that they are not made of one simple component but are the superpositions of these contents. The different scenarios tend to give very different predictions on the production and decay of the scalar mesons which are helpful to determine the dominant component. Although intensive study has been given to the decay property of the scalar mesons, the production of these mesons can provide a different unique insight to the mysterious structure of these mesons, especially their production in B decays.

In B meson decays, the energy release is much large and many channels involving a scalar meson in the final state are open. Since the first observation of the scalar meson $f_0(980)$ in three-body B meson decays $B^- \rightarrow K^- f_0(980) \rightarrow K^-(\pi^+\pi^-)$ [4], the two collaborations, BaBar and Belle, have reported many studies on decays involving a scalar meson in the final state: the branching ratios and/or direct CP asymmetries are measured or set an upper limit [5]. Since much more interesting channels are still not observed at present, it is just the beginning of scalar meson study in B factories. Meanwhile, it is also necessary to provide more theoretical studies which are useful for future experiments.

Theoretically, the studies on hadronic B decays are usually polluted by the nonperturbative QCD effect and predictions on the observables always suffer large uncertainties. Since there is only one hadron in the final state in semileptonic $B \rightarrow S$ decays, they receive less theoretical uncertainties. In these channels, the most challenging part in the calculation is the matrix element of the $B_{(s)}$ to scalar meson transition. In the region of small recoil, where q^2 is large, the form factors are dominated by the soft dynamics, which is out of control of perturbative QCD. However, in the large-recoil region where $q^2 \rightarrow 0$, roughly 5 GeV of energy is released. About half of this energy is taken by the light scalar meson, which suggests that large momentum is transferred in this process and the interaction is mainly dominated by the short-distance dynamics. Therefore

the perturbative QCD approach (PQCD) [6] is expected to be applicable to B to scalar meson transitions in the large-recoil region. With the results obtained in the restricted region, one can extrapolate these form factors to the whole kinematic region by adopting some parametrization form for the form factors.

This paper is organized as following: The distribution amplitudes and decay constants of the mesons are given in Section II. In Section III we listed the formulae about the form factors and semileptonic decays. Section IV are the discussion of the numerical results. The Appendix A lists out the useful functions for PQCD approach.

II. CONVENTIONS AND INPUTS

We will work in the rest frame of the B meson and use the light-cone coordinates. In the heavy quark limit the mass difference of b quark and B meson is negligible: $m_b \simeq m_B$. The masses of scalar mesons are very small compared with the b quark mass, we keep them up to the first order. Since the scalar meson in the final state moves very fast in the large-recoil region, we define the momentum of the scalar meson on the plus direction in the light-cone coordinates. The momentum of B meson and scalar mesons can be denoted as

$$P_B = \frac{m_B}{\sqrt{2}}(1, 1, 0_{\perp}), \quad P_S = \frac{m_B}{\sqrt{2}}(\eta, 0, 0_{\perp}). \quad (1)$$

Then for momentum $q = P_B - P_S$, there exists $\eta = 1 - q^2/m_B^2$. The momentum of the light antiquark in B meson and the quark in scalar mesons are denoted as k_1 and k_2 respectively(see Fig.1):

$$k_1 = (0, \frac{m_B}{\sqrt{2}}x_1, \mathbf{k}_{1\perp}), \quad k_2 = (\frac{m_B}{\sqrt{2}}x_2\eta, 0, \mathbf{k}_{2\perp}). \quad (2)$$

In the course of the PQCD calculations, the light-cone wave functions of the mesons are required. The B meson is a heavy-light system, and its light cone matrix element can be decomposed as [7]

$$\begin{aligned} & \int_0^1 \frac{d^4 z}{(2\pi)^4} e^{ik_1 \cdot z} \langle 0 | b_\beta(0) \bar{q}_\alpha(z) | \bar{B}_{(s)}(P_{B_{(s)}}) \rangle \\ &= \frac{i}{\sqrt{2N_c}} \left\{ (P_{B_{(s)}} + m_{B_{(s)}}) \gamma_5 \left[\phi_{B_{(s)}}(k_1) + \frac{\not{n} - \not{v}}{\sqrt{2}} \bar{\phi}_{B_{(s)}}(k_1) \right] \right\}_{\beta\alpha}, \end{aligned} \quad (3)$$

where $n = (1, 0, \mathbf{0}_T)$ and $v = (0, 1, \mathbf{0}_T)$ are light-like unit vectors. There are two Lorentz structures in B meson light-cone distribution amplitudes, and they obey the normalization conditions:

$$\int \frac{d^4 k_1}{(2\pi)^4} \phi_{B_{(s)}}(k_1) = \frac{f_{B_{(s)}}}{2\sqrt{2N_c}}, \quad \int \frac{d^4 k_1}{(2\pi)^4} \bar{\phi}_{B_{(s)}}(k_1) = 0, \quad (4)$$

with $f_{B_{(s)}}$ as the decay constant of $B_{(s)}$ meson. In principle, both the $\phi_{B_{(s)}}(k_1)$ and $\bar{\phi}_{B_{(s)}}(k_1)$ contribute in B meson transitions. However, the contribution of $\bar{\phi}_{B_{(s)}}(k_1)$ is usually neglected, because its contribution is numerically small [8]. So we will only keep the term with $\phi_{B_{(s)}}(k_1)$ in equation (3). In the momentum space the light cone matrix of B meson can be expressed as:

$$\Phi_{B_{(s)}} = \frac{i}{\sqrt{6}} (P_{B_{(s)}} + m_{B_{(s)}}) \gamma_5 \phi_{B_{(s)}}(k_1). \quad (5)$$

Usually the hard part is independent of k^+ or/and k^- , so we integrate one of them out from $\phi_{B(s)}(k^+, k^-, \mathbf{k}_\perp)$. With b as the conjugate space coordinate of \mathbf{k}_\perp , we can express $\phi_{B(s)}(x, \mathbf{k}_\perp)$ in b-space by

$$\Phi_{B(s),\alpha\beta}(x, b) = \frac{i}{\sqrt{2N_c}} \left[P_{B(s)} \gamma_5 + m_{B(s)} \gamma_5 \right]_{\alpha\beta} \phi_{B(s)}(x, b), \quad (6)$$

where x is the momentum fraction of the light quark in B meson. In this paper, we use the following expression for $\phi_{B(s)}(x, b)$:

$$\phi_{B(s)}(x, b) = N_{B(s)} x^2 (1-x)^2 \exp \left[-\frac{m_{B(s)}^2 x^2}{2\omega_b^2} - \frac{1}{2} (\omega_b b)^2 \right], \quad (7)$$

with $N_{B(s)}$ the normalization factor, which is determined by equation (4). In recent years, a lot of studies for B^\pm and B_d^0 decays have been performed by PQCD approach [6]. With the rich experimental data, the ω_b in (7) is fixed as 0.40GeV. In our calculation, we adopt $\omega_b = (0.40 \pm 0.05)\text{GeV}$ and $f_B = (0.19 \pm 0.025\text{GeV})$ for B mesons. For B_s meson, taking the SU(3) breaking effects into consideration, we adopt $\omega_{b_s} = (0.50 \pm 0.05)\text{GeV}$ and $f_{B_s} = 0.23 \pm 0.03\text{GeV}$ [9].

In the spectroscopy study, many scalar states have been discovered. Among them, the scalar mesons below 1 GeV, including $f_0(600)(\sigma)$, $f_0(980)$, $K_0^*(800)(\kappa)$ and $a_0(980)$, are usually viewed to form an SU(3) nonet; while scalar mesons around 1.5 GeV, including $f_0(1370)$, $f_0(1500)/f_0(1700)$, $K_0^*(1430)$ and $a_0(1450)$, form another nonet. There are two different scenarios to describe these mesons in the quark model. The first one(called scenario 1 in this paper) is the naive 2-quark model: the nonet mesons below 1 GeV are treated as the lowest lying states, and the ones near 1.5 GeV are the first excited state. In this scenario, the flavor wave functions of the light scalar mesons are

$$\begin{aligned} \sigma &= \frac{1}{\sqrt{2}}(u\bar{u} + d\bar{d}), \quad f_0 = s\bar{s}, \\ a_0^+ &= u\bar{d}, \quad a_0^0 = \frac{1}{\sqrt{2}}(u\bar{u} + d\bar{d}), \quad a_0^- = d\bar{u}, \\ \kappa^+ &= u\bar{s}, \quad \kappa^0 = d\bar{s}, \quad \bar{\kappa}^0 = s\bar{d}, \quad \kappa^- = s\bar{u}. \end{aligned} \quad (8)$$

Here it's supposed that the σ and $f_0(980)$ has the ideal mixing. However, the data of J/ψ decays doesn't favor $f_0(980)$ as a pure $s\bar{s}$ state[10], and it seems that σ and $f_0(980)$ have a mixing like

$$\begin{aligned} |f_0(980)\rangle &= |s\bar{s}\rangle \cos\theta + |n\bar{n}\rangle \sin\theta, \\ |\sigma\rangle &= -|s\bar{s}\rangle \sin\theta + |n\bar{n}\rangle \cos\theta, \end{aligned} \quad (9)$$

with $|n\bar{n}\rangle = \frac{1}{\sqrt{2}}(u\bar{u} + d\bar{d})$ and θ as the mixing angle. The above description has encountered several severe difficulties. For example, if the $\bar{q}q$ states have the quantum numbers $J^{PC} = 0^{++}$, the corresponding masses are expected larger than that of the vector mesons. Studies on the mixing angle of σ and $f_0(980)$ [11] show that θ tends to be not a unique value, which indicates that σ and $f_0(980)$ may not be purely $q\bar{q}$ states. Based on these facts, the second scenario is proposed, where the nonet mesons near 1.5GeV are viewed as the lowest lying states, while the mesons below 1 GeV may be viewed as four-quark bound states. Because of the difficulty when dealing with four-quark states, we only do the calculation about the heavier nonet in this scenario.

The decay constants of scalar mesons are defined by[10]

$$\langle S(p)|\bar{q}_2\gamma_\mu q_1|0\rangle = f_S p_\mu, \quad \langle S|\bar{q}_2 q_1|0\rangle = m_S \bar{f}_S. \quad (10)$$

Because of the charge conjugate invariance, neutral scalar mesons cannot be produced by the vector current and thus

$$f_\sigma = f_{f_0} = f_{a_0^0} = 0. \quad (11)$$

For other scalar mesons, the vector decay constant f_S and scalar decay constant \bar{f}_S (listed in Table I and II) is related by equations of motion $\mu_s f_S = \bar{f}_S$, with $\mu_s = \frac{m_S}{m_2(\mu) - m_1(\mu)}$. m_S is the mass of the scalar meson, and m_1, m_2 are the running current quark masses. Inputs of the scalar mesons in our calculation, include the decay constants, running quark masses in this paragraph and the Gegenbauer moments in the following, quote from [10].

The definition of twist-2 light-cone distribution amplitude(LCDA) $\Phi_S(x)$ and twist-3 LCDAs $\Phi_S^s(x)$ and Φ_S^σ for the scalar mesons can be combined into a single matrix element[10]:

$$\begin{aligned} \langle S(P_S) | q(0)_j \bar{q}(z)_l | 0 \rangle &= \frac{-1}{\sqrt{2N_c}} \int_0^1 dx e^{ixp \cdot z} \{ P_S \Phi_S(x) + m_S \Phi_S^s(x) + m_S \sigma_{\mu\nu} P_S^\mu z^\nu \frac{\Phi_S^\sigma(x)}{6} \}_{jl} \\ &= \frac{-1}{\sqrt{2N_c}} \int_0^1 dx e^{ixp \cdot z} \{ P_S \Phi_S(x) + m_S \Phi_S^s(x) + m_S (\not{p} \not{v} - 1) \Phi_S^T(x) \}_{jl}, \end{aligned} \quad (12)$$

with the normalization conditions

$$\begin{aligned} \int_0^1 dx \phi_S(x) &= \frac{f_S}{2\sqrt{2N_c}}, \\ \int_0^1 dx \phi_S^s(x) &= \int_0^1 dx \phi_S^\sigma(x) = \frac{\bar{f}_S}{2\sqrt{2N_c}}. \end{aligned} \quad (13)$$

The LCDAs can be expanded in Gegenbauer polynomials as the following form:

$$\begin{aligned} \phi_S(x) &= \frac{f_S}{2\sqrt{2N_c}} 6x(1-x) \left[1 + \mu_s \sum_{m=1}^{\infty} B_m(\mu) C_m^{3/2}(2x-1) \right], \\ &= \frac{\bar{f}_S}{2\sqrt{2N_c}} 6x(1-x) \left[\frac{1}{\mu_s} + \sum_{m=1}^{\infty} B_m(\mu) C_m^{3/2}(2x-1) \right], \end{aligned} \quad (14)$$

$$\phi_S^s(x) = \frac{\bar{f}_S}{2\sqrt{2N_c}} [1 + \sum_{m=1}^{\infty} a_m(\mu) C_m^{1/2}(2x-1)], \quad (15)$$

$$\phi_S^T(x) = \frac{d}{dx} \frac{\phi_S^\sigma(x)}{6} = \frac{\bar{f}_S}{2\sqrt{2N_c}} \frac{d}{dx} \left\{ x(1-x) [1 + \sum_{m=1}^{\infty} b_m(\mu) C_m^{3/2}(2x-1)] \right\}. \quad (16)$$

where $B_m(\mu)$, $a_m(\mu)$ and $b_m(\mu)$ are the Gegenbauer moments and $C_m^{(3/2)}$ and $C_m^{1/2}$ are the Gegenbauer polynomials. The values of $B_m(\mu)$ are listed in Table I and II. And the values of $b_m \mu$ and $a_m(\mu)$ in scenario 2 are worked out in [20], which is listed in Table III. However, in the calculation in scenario 1, the asymptotic form of twist-3 LCDAs is used.

III. $B \rightarrow S$ FORM FACTORS AND SEMILEPTONIC DECAYS IN THE PQCD APPROACH

A. A Brief Review of pQCD Approach

The basic idea of pQCD approach is including the intrinsic transverse momenta of valence quarks in the calculation of the hadronic matrix elements. The transition matrix element(see Fig.

TABLE I: Decay constants \bar{f}_S (in unit of MeV) and Gegenbauer moments at scale $\mu = 1\text{GeV}$ in scenario 1.

	\bar{f}_S	B_1	B_3
$a_0(980)$	365 ± 20	-0.93 ± 0.10	0.14 ± 0.08

$f_0(980)$	370 ± 20	-0.78 ± 0.08	0.02 ± 0.07
$f_0(1500)$	-255 ± 30	0.80 ± 0.40	-1.32 ± 0.14
$\kappa(800)$	340 ± 20	-0.92 ± 0.11	0.15 ± 0.09
$K_0^*(1430)$	-300 ± 30	0.58 ± 0.07	-1.20 ± 0.08

TABLE II: Decay constants \bar{f}_S (in unit of MeV) and Gegenbauer moments at scale $\mu = 1\text{GeV}$ in scenario 2.

	\bar{f}_S	B_1	B_3
$a_0(1450)$	460 ± 50	-0.58 ± 0.12	-0.49 ± 0.15
$f_0(1500)$	490 ± 50	-0.48 ± 0.11	-0.37 ± 0.20
$K_0^*(1430)$	445 ± 50	-0.57 ± 0.13	-0.42 ± 0.22

1) of B meson to a scalar meson($q_1\bar{q}_2$ component is supposed) can be expressed as the convolution of the wave functions Φ_B , Φ_S and the hard scattering kernel T_H , integrated over the longitudinal and transverse momenta of the valence quarks:

$$\mathcal{M} \propto \int_0^1 dx_1 dx_2 \int_{-\infty}^{\infty} \frac{d^2 \vec{k}_{1\perp}}{(2\pi)^2} \frac{d^2 \vec{k}_{2\perp}}{(2\pi)^2} \Phi_B(x_1, \vec{k}_{1\perp}, p_B, t) T_H(x_1, x_2, \vec{k}_{1\perp}, \vec{k}_{2\perp}, t) \Phi_S(x_2, \vec{k}_{2\perp}, p_1, t). \quad (17)$$

It's convenient to calculate the transition amplitude in coordinate space. Through the Fourier transformation, the above equation becomes

$$\mathcal{M} \propto \int_0^1 dx_1 dx_2 \int_{-\infty}^{\infty} d^2 \vec{b}_1 d^2 \vec{b}_2 \Phi_B(x_1, \vec{b}_1, p_B, t) T_H(x_1, x_2, \vec{b}_1, \vec{b}_2, t) \Phi_S(x_2, \vec{b}_2, p_1, t). \quad (18)$$

In principle, loop corrections to scattering kernel T_H can be taken into consideration, which usually bring two types of infrared divergences in individual diagrams: soft and collinear. Soft divergence is generated when all the components of a loop momentum l go to zero:

$$l^\mu = (l^+, l^-, \vec{l}_T) = (\Lambda, \Lambda, \vec{\Lambda}), \quad (19)$$

TABLE III: Gegenbauer moments for the twist-3 LCDAs of scalar mesons at the scale $\mu = 1\text{GeV}$ in scenario 2[20].

$f_0(1500)$	0	$-0.33 \sim 0.18$	$0.28 \sim 0.79$	0	$-0.15 \sim -0.088$	$0.044 \sim 0.16$

FIG. 1: Contributions to the form factors in the PQCD approach, where the cross denotes the weak vertex.

with l^μ expressed in the light-cone coordinate. The collinear divergence arise from the region where the gluon momentum is parallel to the massless quark momentum:

$$l^\mu = (l^+, l^-, \vec{l}_T) = (m_B, \Lambda^2/m_B, \vec{\Lambda}). \quad (20)$$

In both cases, the loop integration correspond to $\int d^4l/l^4 \sim \log \Lambda$, thus logarithmic divergences are generated. In perturbation theory, it has been shown order by order that these divergences can be separated from the hard kernel and absorbed into meson wave functions using eikonal approximation[12]. When the soft and collinear momenta overlap, one also encounter double logarithm divergences, which can be resummed into the Sudakov factor and its expression is given in Appendix A.

The loop corrections to the weak decay vertex will generate another type of double logarithm. For example, the amplitude of the left diagram of Fig. 1 is proportional to $1/(x_2^2 x_1)$. When $x_2 \rightarrow 0$, additional collinear divergences are associated with the internal quark. The integration of the amplitude will produce double logarithm $\alpha_s \ln^2 x_2$, and the resummation of this type of double logarithm gives rise to Sudakov factor $S_t(x_2)$ [13], which is usually called jet function. The similar jet function $S_t(x_1)$ is generated after the resummation of the same type of double logarithm of the right diagram in Fig. 1. The jet function decreases faster than any power of x as $x \rightarrow 0$, thus it kills the endpoint singularity effectively. The jet function has been parametrized in a form which is independent of the decay channels, twists and flavors[14].

With the Sudakov factors included, the factorization formula of the form factor matrix element in pQCD approach is given by

$$\begin{aligned} \mathcal{M} \propto & \int_0^1 dx_1 dx_2 \int_{-\infty}^{\infty} d^2 \vec{b}_1 d^2 \vec{b}_2 \Phi_B(x_1, \vec{b}_1, p_B, t) T_H(x_1, x_2, \vec{b}_1, \vec{b}_2, t) \\ & \times \Phi_S(x_2, \vec{b}_2, p_1, t) S_t(x_i) \exp[-S_B(t) - S_2(t)]. \end{aligned} \quad (21)$$

B. Form Factors in the PQCD approach

The form factors for $B_{(s)} \rightarrow S$ transition are defined by

$$\kappa_S \langle S(P_S) | \bar{q} \gamma_\mu \gamma_5 b | \overline{B_{(s)}}(P_{B_{(s)}}) \rangle = -i \left\{ \left[(P_{B_{(s)}} + P_S)_\mu - \frac{m_{B_{(s)}}^2 - m_S^2}{q^2} q_\mu \right] F_1(q^2) + \frac{m_{B_{(s)}}^2 - m_S^2}{q^2} q_\mu F_0(q^2) \right\}, \quad (22)$$

$$\kappa_S \langle S(P_S) | \bar{q} \sigma_{\mu\nu} b | \overline{B_{(s)}}(P_{B_{(s)}}) \rangle = -i \epsilon_{\mu\nu\alpha\beta} p_1^\alpha q^\beta \frac{2F_T(q^2)}{m_{B_{(s)}} + m_S}, \quad (23)$$

$$\kappa_S \langle S(P_S) | \bar{q} \sigma_{\mu\nu} \gamma_5 b | \overline{B_{(s)}}(P_{B_{(s)}}) \rangle = [q_\mu P_{S\nu} - P_{S\mu} q_\nu] \frac{2F_T(q^2)}{m_{B_{(s)}} + m_S}, \quad (24)$$

with $q = P_{B_{(s)}} - P_S$. κ_S is the flavor factor for the transition: $\sqrt{2}$ for the component of $\bar{u}u$ in the $\frac{\bar{u}u \pm \bar{d}d}{\sqrt{2}}$ state, $\pm\sqrt{2}$ for the component of $\bar{d}d$ in the $\frac{\bar{u}u \pm \bar{d}d}{\sqrt{2}}$ state, 1 for the other states. In the large-recoil region, a hard gluon is required to kick the soft spectator antiquark to a fast-moving antiquark. Therefore, in this kinematics region, the form factors can be calculated perturbatively. The lowest order diagrams for the $B_{(s)} \rightarrow S$ transition are shown in Fig.1. Carrying out the calculation under pQCD approach, we obtain the analytic formulae of the form factors nearby the $q^2 = 0$:

$$\begin{aligned} F_0(\eta) &= 8\pi C_F m_B^2 \int_0^1 dx_1 dx_2 \int_0^\infty b_1 db_1 b_2 db_2 \phi_B(x_1, b_1) \\ &\quad \times \left\{ [\eta(x_2\eta - \eta - 1)\phi_S(x_2) - r_2\eta(2x_2 - 1)\phi_S^T(x_2) + r_2(2x_2\eta - 3\eta + 2)\phi_S^s(x_2)] \right. \\ &\quad \times h_e(x_1, (1-x_2)\eta, b_1, b_2) \alpha_s(t_e^1) \exp[-S_{ab}(t_e^1)] S_t(x_2) \\ &\quad \left. + 2r_2\eta\phi_S^s(x_2) h_e(1-x_2, x_1\eta, b_2, b_1) \alpha_s(t_e^2) \exp[-S_{ab}(t_e^2)] S_t(x_1) \right\}, \end{aligned} \quad (25)$$

$$\begin{aligned} F_1(\eta) &= 8\pi C_F m_B^2 \int_0^1 dx_1 dx_2 \int_0^\infty b_1 db_1 b_2 db_2 \phi_B(x_1, b_1) \\ &\quad \times \left\{ [(x_2\eta - \eta - 1)\phi_S(x_2) + r_2(-2x_2 + 3 - 2/\eta)\phi_S^T(x_2) - r_2(1 - 2x_2)\phi_S^s(x_2)] \right. \\ &\quad \times h_e(x_1, (1-x_2)\eta, b_1, b_2) \alpha_s(t_e^1) \exp[-S_{ab}(t_e^1)] S_t(x_2) \\ &\quad \left. + 2r_2\phi_S^s(x_2) h_e(1-x_2, x_1\eta, b_2, b_1) \alpha_s(t_e^2) \exp[-S_{ab}(t_e^2)] S_t(x_1) \right\}, \end{aligned} \quad (26)$$

$$\begin{aligned} F_T(\eta) &= 8\pi C_F m_B^2 (1+r_2) \int_0^1 dx_1 dx_2 \int_0^\infty b_1 db_1 b_2 db_2 \phi_B(x_1, b_1) \\ &\quad \times \left\{ [r_2(x_2 - 1)\phi_S^s(x_2) - \phi_S(x_2) + r_2(x_2 - 1 - 2/\eta)\phi_S^T(x_2)] \right. \\ &\quad \times h_e(x_1, (1-x_2)\eta, b_1, b_2) \alpha_s(t_e^1) \exp[-S_{ab}(t_e^1)] S_t(x_2) \\ &\quad \left. + 2r_2\phi_S^s(x_2) h_e(1-x_2, x_1\eta, b_2, b_1) \alpha_s(t_e^2) \exp[-S_{ab}(t_e^2)] S_t(x_1) \right\}. \end{aligned} \quad (27)$$

With these formulae we calculate the form factors nearby $q^2 = 0$. Through fitting the results among the region $0 < q^2 < 10\text{GeV}^2$, we extrapolate them with the pole model parametrization

$$F_i(q^2) = \frac{F_i(0)}{1 - a(q^2/m_B^2) + b(q^2/m_B^2)^2}, \quad (28)$$

with a, b are the constants to be determined from the fitting procedure.

C. Semileptonic $B_{(s)}$ Meson decays

The effective Hamiltonian for $b \rightarrow ul\bar{\nu}_l$ transition is

$$\mathcal{H}_{eff}(b \rightarrow ul\bar{\nu}_l) = \frac{G_F}{\sqrt{2}} V_{ub} \bar{u} \gamma_\mu (1 - \gamma_5) b \bar{l} \gamma^\mu (1 - \gamma_5) \nu_l. \quad (29)$$

With the Hamiltonian, the q^2 dependant decay width $\frac{d\Gamma}{dq^2}$ can be expressed as

$$\begin{aligned} \frac{d\Gamma}{dq^2} &= \frac{G_F^2 |V_{ub}|^2}{192\pi^3 m_B^3} \frac{q^2 - m_l^2}{(q^2)^2} \sqrt{\frac{(q^2 - m_l^2)^2}{q^2}} \sqrt{\frac{(m_B^2 - m_S^2 - q^2)^2}{4q^2} - m_S^2} \\ &\quad \left[(m_l^2 + 2q^2)(q^2 - (m_B - m_S)^2)(q^2 - (m_B + m_S)^2) F_1^2(q^2) + 3m_l^2(m_B^2 - m_S^2)^2 F_0^2(q^2) \right] \end{aligned} \quad (30)$$

with m_l as the mass of the lepton.

The calculation of $b \rightarrow sl^+l^-$ transition is a bit complicated, because both the short-distance and long-distance contribution should be taken into consideration. The weak effective Hamiltonian is

$$\mathcal{H}_{\text{eff}} = -\frac{G_F}{\sqrt{2}} V_{tb} V_{ts}^* \sum_{i=1}^{10} C_i(\mu) O_i(\mu), \quad (31)$$

with the doubly CKM suppressed terms omitted. $C_i(\mu)$ are the Wilson coefficients and the local operators $O_i(\mu)$ are given by [16]

$$\begin{aligned} O_1 &= (\bar{s}_\alpha c_\alpha)_{V-A} (\bar{c}_\beta b_\beta)_{V-A}, \quad O_2 = (\bar{s}_\alpha c_\beta)_{V-A} (\bar{c}_\beta b_\alpha)_{V-A}, \\ O_3 &= (\bar{s}_\alpha b_\alpha)_{V-A} \sum_q (\bar{q}_\beta q_\beta)_{V-A}, \quad O_4 = (\bar{s}_\alpha b_\beta)_{V-A} \sum_q (\bar{q}_\beta q_\alpha)_{V-A}, \\ O_5 &= (\bar{s}_\alpha b_\alpha)_{V-A} \sum_q (\bar{q}_\beta q_\beta)_{V+A}, \quad O_6 = (\bar{s}_\alpha b_\beta)_{V-A} \sum_q (\bar{q}_\beta q_\alpha)_{V+A}, \\ O_7 &= \frac{em_b}{8\pi^2} \bar{s} \sigma^{\mu\nu} (1 + \gamma_5) b F_{\mu\nu}, \\ O_9 &= \frac{\alpha_{\text{em}}}{8\pi} (\bar{l} \gamma_\mu l) (\bar{s} \gamma^\mu (1 - \gamma_5) b), \quad O_{10} = \frac{\alpha_{\text{em}}}{8\pi} (\bar{l} \gamma_\mu \gamma_5 l) (\bar{s} \gamma^\mu (1 - \gamma_5) b), \end{aligned} \quad (32)$$

where $(\bar{q}_1 q_2)_{V-A} (\bar{q}_3 q_4)_{V-A} \equiv (\bar{q}_1 \gamma^\mu (1 - \gamma_5) q_2) (\bar{q}_3 \gamma_\mu (1 - \gamma) q_4)$, and $(\bar{q}_1 q_2)_{V-A} (\bar{q}_3 q_4)_{V+A} \equiv (\bar{q}_1 \gamma^\mu (1 - \gamma_5) q_2) (\bar{q}_3 \gamma_\mu (1 + \gamma) q_4)$. In equation (32), the term suppressed by m_s in O_7 is neglected.

The amplitude for $b \rightarrow sl^+l^-$ transition can be decomposed as

$$\begin{aligned} \mathcal{A}(b \rightarrow sl^+l^-) &= \frac{G_F}{2\sqrt{2}} \frac{\alpha_{\text{em}}}{\pi} V_{ts}^* V_{tb} \left\{ C_9^{\text{eff}}(\mu) [\bar{s} \gamma_\mu (1 - \gamma_5) b] [\bar{l} \gamma^\mu l] + C_{10} [\bar{s} \gamma_\mu (1 - \gamma_5) b] [\bar{l} \gamma^\mu \gamma_5 l] \right. \\ &\quad \left. - 2m_b C_7^{\text{eff}}(\mu) [\bar{s} i \sigma_{\mu\nu} \frac{q^\nu}{q^2} (1 + \gamma_5) b] [\bar{l} \gamma^\mu l] \right\}, \end{aligned} \quad (33)$$

where $\hat{s} = q^2/m_B^2$ and $\hat{m}_b = m_b/m_B$, with m_b as the b quark mass in the $\overline{\text{MS}}$ scheme. The long-distance and short-distance contributions are absorbed into the $C_7^{\text{eff}}(\mu)$ and $C_9^{\text{eff}}(\mu)$, with

$$\begin{aligned} C_7^{\text{eff}}(\mu) &= C_7(\mu) + C'_{b \rightarrow s\gamma}(\mu), \\ C_9^{\text{eff}}(\mu) &= C_9(\mu) + Y_{\text{pert}}(\hat{s}) + Y_{\text{LD}}(\hat{s}). \end{aligned} \quad (34)$$

Y_{pert} represents the perturbative contributions, and Y_{LD} is the long-distance part. The Y_{pert} is given by[17]

$$\begin{aligned} Y_{\text{pert}}(\hat{s}) &= h(\hat{m}_c, \hat{s}) C_0 - \frac{1}{2} h(1, \hat{s}) (4C_3 + 4C_4 + 3C_5 + C_6) \\ &\quad - \frac{1}{2} h(0, \hat{s}) (C_3 + 3C_4) + \frac{2}{9} (3C_3 + C_4 + 3C_5 + C_6), \end{aligned} \quad (35)$$

with $C_0 = C_1 + 3C_2 + 3C_3 + C_4 + 3C_5 + C_6$. The Wilson coefficients, listed in table IV, are given in the leading logarithmic accuracy. The long-distance part Y_{LD} , involving the contributions of $B_{(s)} \rightarrow SV(c\bar{c})$ resonances where $V(c\bar{c})$ are the charmonium states, is neglected in this paper because of the lack of the experimental data. The corrections of the nonfactorizable effects of the charm quark loop to the $b \rightarrow s\gamma$ transition at $q^2 = 0$ are also neglected. And the absorptive part of $b \rightarrow s\gamma$ with neglecting the small contribution from $V_{tb} V_{ts}^*$ is represented by the $C'_{b \rightarrow s\gamma}$ part in C_7^{eff} , which is given by(for a complete expression of $C_7^{\text{eff}}(\mu)$, see [19])

$$C'_{b \rightarrow s\gamma}(\mu) = i\alpha_s \left[\frac{2}{9} \eta^{14/23} (G_I(x_t) - 0.1687) - 0.03 C_2(\mu) \right], \quad (36)$$

TABLE IV: The values of Wilson coefficients $C_i(m_b)$ in the leading logarithmic approximation in Standard Model, with $m_W = 80.4\text{GeV}$, $m_t = 173.8\text{GeV}$, $m_b = 4.8\text{GeV}$.[18]

with $G_I(x_t) = \frac{x_t(x_t^2 - 5x_t - 2)}{8(x_t - 1)^3} + \frac{3x_t^2 \ln^2 x_t}{4(x_t - 1)^4}$, $\eta = \alpha_s(m_W)/\alpha_s(\mu)$ and $x_t = m_t^2/m_W^2$.

The q^2 dependant width of $B \rightarrow Sl^+l^-$ is given by

$$\begin{aligned}
 \frac{d\Gamma}{dq^2} &= \frac{G_F^2 \alpha_{em}^2 |V_{tb}|^2 |V_{ts}^*|^2 \sqrt{\lambda}}{1024 m_B^3 \pi^5} \sqrt{\frac{q^2 - 4m_l^2}{q^2}} \\
 &\times \left[\frac{4}{3} \lambda \left| \frac{C_9^{\text{eff}}}{2} F_1(q^2) + \frac{C_{10}}{2} F_1(q^2) \sqrt{\frac{q^2 - 4m_l^2}{q^2}} + C_7^{\text{eff}} \frac{m_b F_T(q^2)}{m_B + m_S} \right|^2 \right. \\
 &+ \frac{4}{3} \lambda \left| \frac{C_9^{\text{eff}}}{2} F_1(q^2) - \frac{C_{10}}{2} F_1(q^2) \sqrt{\frac{q^2 - 4m_l^2}{q^2}} + C_7^{\text{eff}} \frac{m_b F_T(q^2)}{m_B + m_S} \right|^2 \\
 &\left. + \frac{4\lambda}{3q^2} \left| C_9^{\text{eff}} m_l F_1(q^2) + C_7^{\text{eff}} \frac{2m_l^2 m_b F_T(q^2)}{m_B + m_S} \right|^2 + 4 \left| m_l C_{10} (m_B^2 - m_S^2) F_0(q^2) \right|^2 \right], \quad (37)
 \end{aligned}$$

with $\lambda = (m_B^2 - q^2 - m_S^2)^2 - 4m_S^2 q^2$.

IV. NUMERICAL RESULTS AND DISCUSSION

A. Form Factors

Our results of the $B \rightarrow S$ form factors are listed in table V and VI. The errors for the form factors in those two tables arise from the uncertainties of hadronic parameters of $B_{(s)}$ meson(f_B and

TABLE VI: Form factors for $B \rightarrow S$ in scenario 2, with the same error sources as the data in Table V.

	$F_0(0) = F_1(0)$	$F_T(0)$	$a(F_0)$	$b(F_0)$	$a(F_1)$	$b(F_1)$	$a(F_T)$	$b(F_T)$

ω_b), $\Lambda_{\text{QCD}}(0.20\text{GeV}-0.30\text{GeV})$, factorization scales(see Eqs.(A1)) and the Gegenbauer moments of scalar mesons. A number of remarks will be given in order.

- Compared with transitions of B meson to pseudoscalar mesons, vector mesons and axial-vector mesons [8, 15], our predictions on $B \rightarrow S$ form factors in scenario 2 are obviously larger, which is caused mainly by the large decay constants(\bar{f}_S) of the scalar mesons. For example, the form factor $F_0(0)$ of B meson to pion transition is about 0.23[9] with 0.131GeV as the decay constant of pion, while the B meson to $a_0(980)$ transition in scenario 1 has 0.39 as its corresponding form factor, whose decay constant is more than two times larger than pion.
- In Table V, the form factors of $B \rightarrow \sigma$ are smaller than those of $B \rightarrow a_0(980)$. Because the same decay constant and Gegenbauer moments for these two particles are used in the calculation, the differences are caused by the mass differences between $a_0(980)$ and $\sigma(0.98\text{GeV}$ for $a_0(980)$ and 0.513GeV for σ [1]). In scenario 1, there are small differences between $\kappa(800)$ and $f_0(600)$ in masses(0.672GeV for $\kappa(800)$), decay constants and Gegenbauer moments. Besides, the contribution from twist-2 LCDA of $\kappa(800)$, which is proportional to f_S , is too small to give sizable differences. Thus the $B \rightarrow \sigma$ and $B \rightarrow \kappa(800)$ have nearly the same form factors as shown in Table V. Comparing the form factors of $B \rightarrow \kappa(800)$ with $\bar{B}_s^0 \rightarrow \kappa(800)$ in Table V, one can find that the differences between B and \bar{B}_s^0 mesons affect little. Therefore, the large differences between the form factors of $\bar{B}_s^0 \rightarrow \kappa(800)$ and those of $B \rightarrow a_0(980)$ are mainly due to the large difference between the scalar meson masses.
- The form factors of B to heavier nonet transition in scenario 1 are negative, while the others are positive. The reason is that the decay constants(\bar{f}_S) of the heavier nonet in scenario 1 have opposite signs to the others, which is clearly shown in Table I and II.
- As we can see from the table V and VI, the predictions in scenario 2 are larger than the corresponding ones in scenario 1 roughly by a factor of 2 in magnitude. In order to show how these large differences are generated, we take the form factor $F_0(0)$ as an example and list contributions from different terms in LCDAs in Table VII(Data is given with asymptotic forms of twist-3 LCDAs are adopted in both scenario 1 and scenario 2, because the terms with Gegenbauer moments bring so small effects, which is discussed in the following, that they can't change the argument). The contributions from the two twist-3 LCDAs ϕ_S^s and ϕ_S^T are given in the first two columns. The numbers in the column ' B_1 ' denotes the contributions from the Gegenbauer moments B_1 in twist-2 LCDAs. It is also similar for the fourth B_3 column. The last column collects the total contributions to the form factors. The different inputs between in scenario 1 and in scenario 2 are the decay constants and Gegenbauer moments. If only twist-3 LCDAs are taken into account, the form factors will be proportional

to the decay constant. Since the decay constants \bar{f}_S in S2 are (typically 60%) larger than those in S1 in magnitude, the form factors are accordingly larger. The ϕ_S^s term give much larger contributions than the ϕ_S^T term. Contributions from the Gegenbauer moments of the twist-2 LCDAs sizably enhance the form factors in S2 but not too much in S1. For B to scalar meson transitions in scenario 1, the B_1 terms provide contributions with the same sign with the twist-3 terms, while the terms with B_3 have the opposite sign. Thus the two terms of the twist-2 LCDAs give destructive contributions to the total form factors in S1. The situation is different in S2, although the two Gegenbauer moments are small in magnitude, they give constructive contributions and induce much larger form factors.

- We also investigate the contributions from terms with Gegenbauer moments in twist-3 LCDAs, and find that the effects brought by these moments are not large. Taking $B \rightarrow f_0(1370)$ transition as an example, a comparison between the cases with and without these contributions is given in Table VIII. We can see that most of the results are changed by less than 10%.
- Compared with our previous study on $B \rightarrow f_0, K_0^*(1430)$ transitions [21, 22], the predictions for the form factors given in the present work are a bit smaller. The main reason is that different values for the threshold resummation parameters c have been used. Moreover, the form factors in this paper are larger than those obtained in other approaches or models[27, 28, 29, 30]. As a result, the branching ratios of the semileptonic decays are larger, which is discussed in the following.

As we have mentioned in the introduction section, the experimentalists have already provided many investigations on nonleptonic B decays involving a scalar meson in the final state. Among these decays, the so-called color-allowed tree-dominated processes can be directly utilized to estimate the $B \rightarrow S$ form factors, under the hypothesis of factorization. For example, the $\bar{B}^0 \rightarrow a_0^+ \pi^-$ decay amplitude in the factorization scheme is expressed as:

$$\begin{aligned} \mathcal{A}(\bar{B}^0 \rightarrow a_0^+ \pi^-) = & \frac{G_F}{\sqrt{2}} m_B^2 f_\pi F_0^{B \rightarrow a_0} \{ V_{ub} V_{ud}^* [a_1 + a_4 + a_{10} - r_\pi(a_6 + a_8)] \\ & + V_{cb} V_{cd}^* [a_4 + a_{10} - r_\pi(a_6 + a_8)] \}, \end{aligned} \quad (38)$$

where a_i is the combination of Wilson coefficient

$$\begin{aligned} a_1 &= C_2 + C_1/3, \quad a_2 = C_1 + C_2/3, \\ a_i &= C_i + C_{i+1}/N_c \quad (i = 3, 5, 7, 9), \\ a_i &= C_i + C_{i-1}/N_c \quad (i = 4, 6, 8, 10). \end{aligned} \quad (39)$$

$a_1 \sim 1$, and it has small uncertainties. Although there are large uncertainties for a_3-a_{10} , the combination of Wilson coefficients satisfies:

$$a_1 \gg \max[a_3-a_{10}]. \quad (40)$$

If only the branching ratios are concerned, contributions from the penguin operators (a_{3-10} terms) can be safely neglected and thus

$$\mathcal{A}(\bar{B}^0 \rightarrow a_0^+ \pi^-) = \frac{G_F}{\sqrt{2}} m_B^2 f_\pi F_0^{B \rightarrow a_0} V_{ub} V_{ud}^* a_1. \quad (41)$$

If the partial decay widths are well determined experimentally, these results will directly constrain the B to scalar meson transition form factors. The upper bounds for $B \rightarrow a_0 \pi$ are given as (in unit

TABLE VII: Contributions from different LCDAs to the $B \rightarrow S$ form factor F_0 in scenario 1 (S1) or scenario 2 (S2). The contributions from the two twist-3 LCDAs ϕ_S^s and ϕ_S^T are given in the first two columns. The numbers in the column' B_1 ' denotes the contributions from the Gegenbauer moments B_1 in twist-2 LCDAs. It is also similar for the fourth column. The last column collects the total contributions to the form factors(Data is given with asymptotic forms of twist-3 LCDAs adopted in both scenario 1 and scenario 2).

$0.63_{-0.14}^{+0.23}$	$0.76_{-0.17}^{+0.37}$	$0.70_{-0.11}^{+0.05}$	$-0.14_{-0.09}^{+0.02}$	$1.60_{-0.05}^{+0.15}$	$0.53_{-0.09}^{+0.18}$	$1.63_{-0.05}^{+0.07}$	$0.57_{-0.07}^{+0.07}$
$0.67_{-0.14}^{+0.17}$	$0.83_{-0.18}^{+0.21}$	$0.71_{-0.07}^{+0.02}$	$-0.12_{-0.11}^{+0.00}$	$1.64_{-0.05}^{+0.04}$	$0.57_{-0.07}^{+0.04}$	$1.65_{-0.04}^{+0.05}$	$0.59_{-0.03}^{+0.07}$

of 10^{-6}):

$$\begin{aligned} \mathcal{BR}(B \rightarrow a_0^\pm(980)\pi^\mp) &< 3.1, \\ \mathcal{BR}(B \rightarrow a_0^\pm(1450)\pi^\mp) &< 2.3, \end{aligned} \quad (42)$$

where the daughter BF has taken to be 100%. Since the scalar mesons $a_0(980)$ and $a_0(1450)$ have vanishing decay constants in the isospin limit, the branching ratios of $\bar{B}^0 \rightarrow a_0^- \pi^+$ are very small and one expects the relation: $\mathcal{BR}(B \rightarrow a_0^\pm \pi^\mp) = \mathcal{BR}(\bar{B}^0 \rightarrow a_0^\pm \pi^\mp)$. Compared with the branching ratio of $\bar{B}^0 \rightarrow \pi^+ \pi^-$ (in unit of 10^{-6})

$$\mathcal{BR}(B \rightarrow \pi^+ \pi^-) = 5.16 \pm 0.22, \quad (43)$$

results provide the upper bound for the $B \rightarrow a_0$ form factors:

$$F_0(B \rightarrow a_0(980)) < 0.78F_0(B \rightarrow \pi) = 0.18, \quad F_0(B \rightarrow a_0(1450)) < 0.67F_0(B \rightarrow \pi) = 0.15, \quad (44)$$

where as an rough estimation, we have taken $F_0(B \rightarrow \pi) = 0.23[9]$. Compared with our results in Table V and VI, one can see our results have exceeded the present experimental upper bound. Despite of that, it does not mean our predictions are ruled out by the data, as the daughter decay is not taken into account in the derivation for the experimental bound. Our predictions will be confronted with the real bound in the future, whenever the daughter decay of a_0 is well studied.

TABLE IX: The total branching ratios for the $b \rightarrow ul\bar{\nu}_l$ in scenario 1(Unit: 10^{-4}). The errors are estimated with errors from the form factors.

B. Decay widths and branching fractions

With the form factors at hand, one can directly obtain the partial decay width through Eq. (30) and Eq. (37). Since masses of electrons and muons are very small compared with q^2 in most kinematic region of the semileptonic decays, they will not produce large effects and are neglected in this work. In Fig. 2 and 3, we give our predictions on the partial decay width of $B_{(s)} \rightarrow Sl^-\bar{\nu}_l$ ($l = e, \mu$) and $B_{(s)} \rightarrow S\tau^-\bar{\nu}_l$, respectively. The diagrams in Fig. 4 and Fig. 5 are similar but for the $B_{(s)} \rightarrow Sl^+l^-$ ($l = e, \mu$) and $B_{(s)} \rightarrow S\tau^+\tau^-$ decays. In Fig. 4, there exists a small discontinuity in each diagram, which is caused by the discontinuities in functions $h(\hat{m}_c, \hat{s})$ and $h(1, \hat{s})$ in Eqs. (35). When $l = \tau$ in Fig. 5, the discontinuities in the diagrams disappear, because the origins of q^2 axes become $4m_\tau^2$ which is large enough to ensure that the variation of q^2 does not pass the discontinuities in the $h(\hat{m}_c, \hat{s})$ and $h(1, \hat{s})$ functions.

The results for the total branching ratios are collected in Table IX, X, XI and XII, with the errors estimated with the errors of the form factors. One can find that the branching ratios with τ lepton(s) in the final state are smaller than the ones without τ lepton(s), because the large mass of τ lepton(s) makes the phase space much smaller. In Table IX, $\frac{Br(B_{(s)} \rightarrow Se\bar{\nu}_e)}{Br(B_{(s)} \rightarrow S\tau\bar{\nu}_\tau)}$ is smaller than two when the scalar meson belongs to the light nonet. While for the heavy nonet mesons, the value of this ratio is larger than two. The reason is that more energy is released when the final state is a light meson, and thus the effect of m_τ on the phase space is not so evident. In Table X and XII, we also list the predictions in light-cone sum rules(LCSR) and QCD sum rules(QCDSR), which are smaller than our predictions. The reason is that we have bigger form factors. Taking

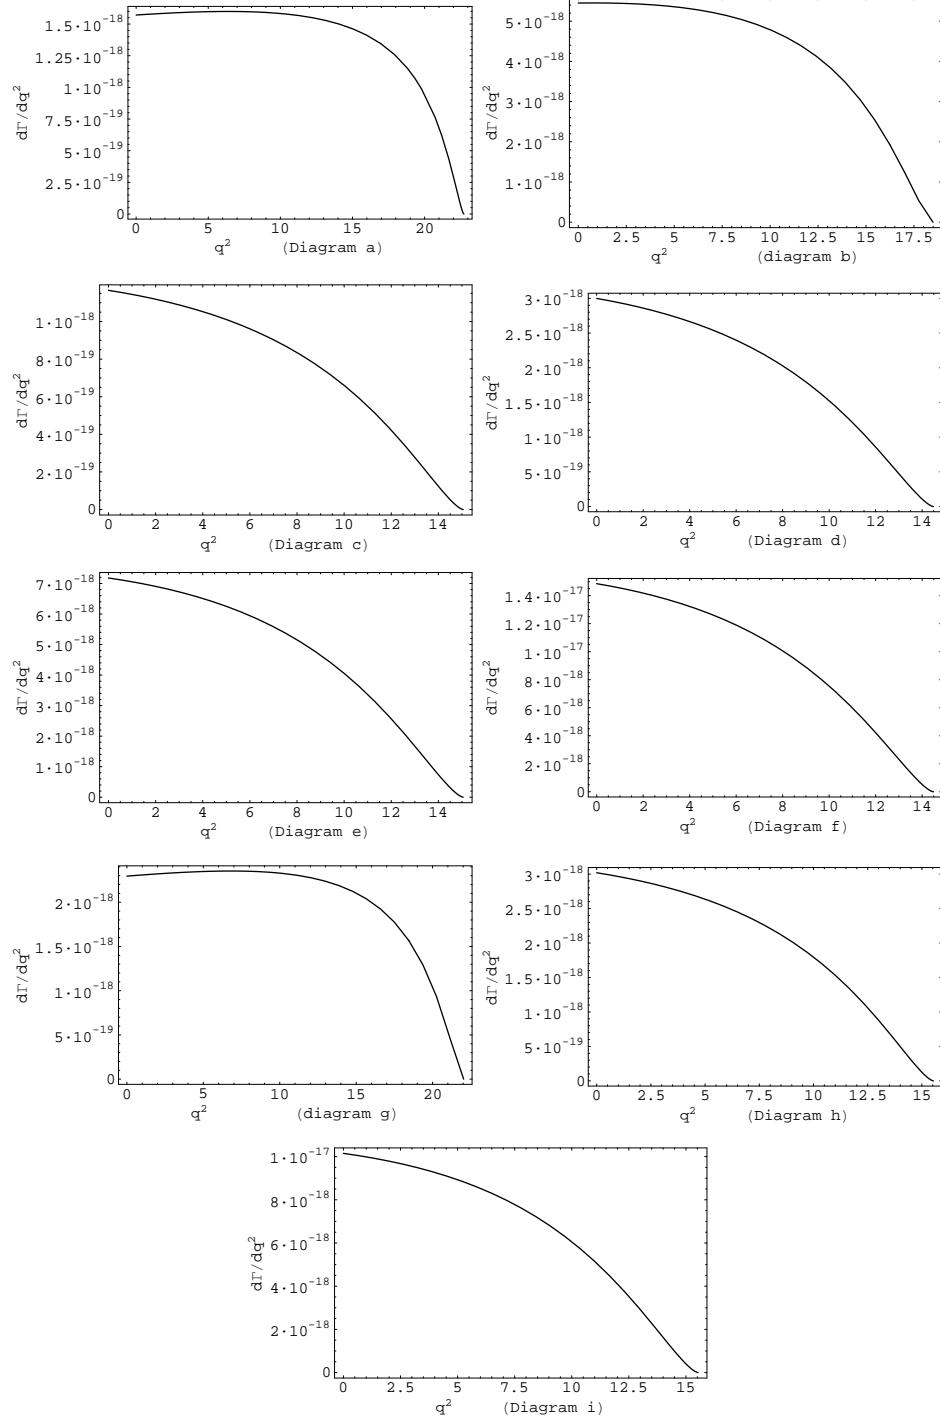

FIG. 2: Partial decay widths of the semileptonic $B \rightarrow Sl\bar{\nu}$ decays as functions of q^2 . Diagram a-d denote the $B^- \rightarrow (\sigma, a_0^+(980), f_0(1370), a_0^+(1450))l^-\bar{\nu}_l$ in scenario 1 respectively; Diagram e-f denote the $B^- \rightarrow (f_0(1370), a_0^+(1450))l^-\bar{\nu}_l$ in scenario 2 respectively; Diagram g: $\bar{B}_s \rightarrow \kappa^+(800)l^-\bar{\nu}_l$ in scenario 1; Diagram h: $\bar{B}_s \rightarrow K_0^{*+}(1430)l^-\bar{\nu}_l$ in scenario 1; Diagram i: $\bar{B}_s \rightarrow K_0^{*+}(1430)l^-\bar{\nu}_l$ in scenario 2.

V. CONCLUSIONS

In this work, we have studied the $B \rightarrow S$ form factors in the PQCD approach under two different scenarios for the scalar mesons. In scenario 1, both of the light and heavy nonet are described as the $\bar{q}q$ state while in scenario 2, we have only studied the heavy nonet. Due to the large decay constant

\bar{f}_S , we have found that most of our predictions are larger than those for the $B \rightarrow P$ transition form factors, especially in scenario 2. Contributions from various LCDAs are explicitly specified. Due to the large masses of $a_0(1450)$, $K_0^*(1430)$, $f_0(1500)$, their twist-3 LCDAs have provided more than one half contributions to the form factors in both scenarios. In scenario 1, the two Gegenbauer moments B_1, B_3 for the twist-2 LCDAs have different signs and they give destructive contributions to the form factors; while in scenario 2, although the two Gegenbauer moments are small in magnitudes, they give constructive contributions and induce larger form factors. Contributions from terms with Gegenbauer moments in the twist-3 LCDAs are also investigated, and we find that these terms do not give large changes. We also study the semileptonic $B \rightarrow Sl\bar{\nu}$ and $B \rightarrow Sl^+l^-$ decays, including the partial decay width and the integrated branching fractions. Branching ratios of the semileptonic $B \rightarrow Sl\bar{\nu}$ decays are found to have the order of 10^{-4} , while branching fractions of the $B \rightarrow Sl^+l^-$ decays have the order of 10^{-7} . Compared with results in the previous studies, our predictions are a bit larger which is caused by larger form factors. These predictions will be tested by the future experiments.

APPENDIX A: PQCD FUNCTIONS

In this part, we collect the functions which are essential in the PQCD calculation.

$$t_e^1 = \max(t_c \sqrt{(1-x_2)\eta} m_B, 1/b_1, 1/b_2), t_e^2 = \max(t_c \sqrt{x_1\eta} m_B, 1/b_1, 1/b_2), \quad (A1)$$

with $t_c = 1$ for the calculation of the central values and $t_c = 0.75-1.25$ for error estimation.

$$\begin{aligned} h_e(x_1, x_2, b_1, b_2) = & K_0(\sqrt{x_1 x_2} m_B b_1) \left[\theta(b_1 - b_2) K_0(\sqrt{x_2} m_B b_1) I_0(\sqrt{x_2} m_B b_2) \right. \\ & \left. + \theta(b_2 - b_1) K_0(\sqrt{x_2} m_B b_2) I_0(\sqrt{x_2} m_B b_1) \right]. \end{aligned} \quad (A2)$$

$$S_t(x) = \frac{2^{1+2c}\Gamma(3/2+c)}{\sqrt{\pi}\Gamma(1+c)} [x(1-x)]^c, \quad (A3)$$

with $c = 0.4$. The Sudakov factor in Eqs.(25)-Eqs.(27) is given by

$$S_{ab}(t) = S_B(t) + S_S(t), \quad (A4)$$

where

$$S_B(t) = s \left(x_1 \frac{m_B}{\sqrt{2}}, b_1 \right) + \frac{5}{3} \int_{1/b_1}^t \frac{d\bar{\mu}}{\bar{\mu}} \gamma_q(\alpha_s(\bar{\mu})), \quad (A5)$$

$$S_S(t) = s \left(x_2 \frac{m_B}{\sqrt{2}}, b_2 \right) + s \left((1-x_2) \frac{m_B}{\sqrt{2}}, b_2 \right) + 2 \int_{1/b_2}^t \frac{d\bar{\mu}}{\bar{\mu}} \gamma_q(\alpha_s(\bar{\mu})), \quad (A6)$$

with the quark anomalous dimension $\gamma_q = -\alpha_s/\pi$. The explicit form for the function $s(Q, b)$ is:

$$\begin{aligned} s(Q, b) = & \frac{A^{(1)}}{2\beta_1} \hat{q} \ln \left(\frac{\hat{q}}{\hat{b}} \right) - \frac{A^{(1)}}{2\beta_1} \left(\hat{q} - \hat{b} \right) + \frac{A^{(2)}}{4\beta_1^2} \left(\frac{\hat{q}}{\hat{b}} - 1 \right) - \left[\frac{A^{(2)}}{4\beta_1^2} - \frac{A^{(1)}}{4\beta_1} \ln \left(\frac{e^{2\gamma_E}-1}{2} \right) \right] \ln \left(\frac{\hat{q}}{\hat{b}} \right) \\ & + \frac{A^{(1)}\beta_2}{4\beta_1^3} \hat{q} \left[\frac{\ln(2\hat{q})+1}{\hat{q}} - \frac{\ln(2\hat{b})+1}{\hat{b}} \right] + \frac{A^{(1)}\beta_2}{8\beta_1^3} \left[\ln^2(2\hat{q}) - \ln^2(2\hat{b}) \right], \end{aligned} \quad (\text{A7})$$

where the variables are defined by

$$\hat{q} \equiv \ln[Q/(\sqrt{2}\Lambda)], \quad \hat{b} \equiv \ln[1/(b\Lambda)], \quad (\text{A8})$$

and the coefficients $A^{(i)}$ and β_i are

$$\begin{aligned} \beta_1 &= \frac{33 - 2n_f}{12}, \quad \beta_2 = \frac{153 - 19n_f}{24}, \\ A^{(1)} &= \frac{4}{3}, \quad A^{(2)} = \frac{67}{9} - \frac{\pi^2}{3} - \frac{10}{27}n_f + \frac{8}{3}\beta_1 \ln\left(\frac{1}{2}e^{\gamma_E}\right), \end{aligned} \quad (\text{A9})$$

n_f is the number of the quark flavors and γ_E is the Euler constant. We will use the one-loop running coupling constant, i.e. we pick up only the four terms in the first line of the expression for the function $s(Q, b)$.
